

Chapter 2

Application Layer

A note on the use of these Powerpoint slides:

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

Computer Networking: A Top Down Approach

7th edition

Jim Kurose, Keith Ross

Pearson/Addison Wesley

April 2016

CS 280 Lecture 5: Application Layer Video Streaming/CDN, Socket Programming

John Magee
26 September 2016

Chapter 2: outline

Previously

2.1 principles of network applications

2.2 Web and HTTP

2.3 electronic mail

- SMTP, POP3, IMAP

2.4 DNS

2.5 P2P applications

This lecture:

2.6 video streaming and content distribution networks (CDNs)

2.7 socket programming with UDP and TCP

Video Streaming and CDNs: context

- video traffic: major consumer of Internet bandwidth
 - Netflix, YouTube: 37%, 16% of downstream residential ISP traffic
 - ~1B YouTube users, ~75M Netflix users
- challenge: scale - how to reach ~1B users?
 - single mega-video server won't work (why?)
- challenge: heterogeneity
 - different users have different capabilities (e.g., wired versus mobile; bandwidth rich versus bandwidth poor)
- *solution*: distributed, application-level infrastructure

Multimedia: video

- video: sequence of images displayed at constant rate
 - e.g., 24 images/sec
- digital image: array of pixels
 - each pixel represented by bits
- coding: use redundancy *within* and *between* images to decrease # bits used to encode image
 - spatial (within image)
 - temporal (from one image to next)

spatial coding example: instead of sending N values of same color (all purple), send only two values: color value (purple) and number of repeated values (N)

frame i

temporal coding example: instead of sending complete frame at $i+1$, send only differences from frame i

frame $i+1$

Multimedia: video

- **CBR: (constant bit rate):**
video encoding rate fixed
- **VBR: (variable bit rate):**
video encoding rate changes
as amount of spatial,
temporal coding changes
- **examples:**
 - MPEG I (CD-ROM) 1.5 Mbps
 - MPEG2 (DVD) 3-6 Mbps
 - MPEG4 (often used in Internet, < 1 Mbps)

spatial coding example: instead of sending N values of same color (all purple), send only two values: color value (purple) and number of repeated values (N)

frame i

temporal coding example: instead of sending complete frame at $i+1$, send only differences from frame i

frame $i+1$

Streaming stored video:

simple scenario:

Streaming multimedia: DASH

- *DASH*: *D*ynamic, *A*daptive *S*treaming over *H*TTP
- *server*:
 - divides video file into multiple chunks
 - each chunk stored, encoded at different rates
 - *manifest file*: provides URLs for different chunks
- *client*:
 - periodically measures server-to-client bandwidth
 - consulting manifest, requests one chunk at a time
 - chooses maximum coding rate sustainable given current bandwidth
 - can choose different coding rates at different points in time (depending on available bandwidth at time)

Streaming multimedia: DASH

- *DASH: Dynamic, Adaptive Streaming over HTTP*
- “intelligence” at client: client determines
 - *when* to request chunk (so that buffer starvation, or overflow does not occur)
 - *what encoding rate* to request (higher quality when more bandwidth available)
 - *where* to request chunk (can request from URL server that is “close” to client or has high available bandwidth)

Content distribution networks

- *challenge*: how to stream content (selected from millions of videos) to hundreds of thousands of *simultaneous* users?
- *option 1*: single, large “mega-server”
 - single point of failure
 - point of network congestion
 - long path to distant clients
 - multiple copies of video sent over outgoing link

....quite simply: this solution *doesn't scale*

Content distribution networks

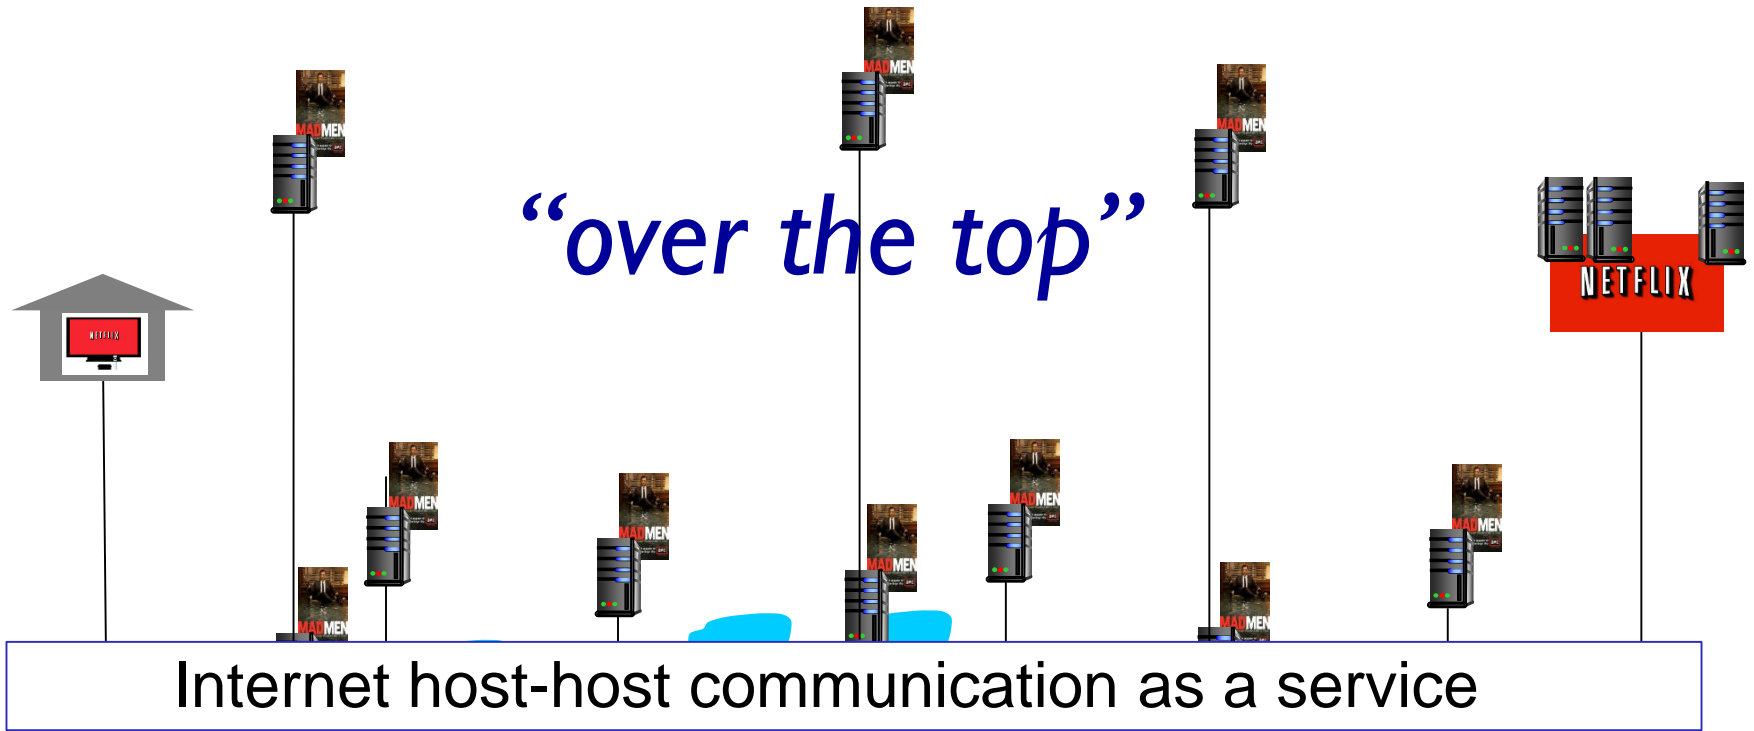

- *challenge*: how to stream content (selected from millions of videos) to hundreds of thousands of simultaneous users?
- *option 2*: store/serve multiple copies of videos at multiple geographically distributed sites (*CDN*)
 - *enter deep*: push CDN servers deep into many access networks
 - close to users
 - used by Akamai, 1700 locations
 - *bring home*: smaller number (10's) of larger clusters in POPs near (but not within) access networks
 - used by Limelight

Content Distribution Networks (CDNs)

- CDN: stores copies of content at CDN nodes
 - e.g. Netflix stores copies of MadMen
- subscriber requests content from CDN
 - directed to nearby copy, retrieves content
 - may choose different copy if network path congested

Content Distribution Networks (CDNs)

OTT challenges: coping with a congested Internet

- from which CDN node to retrieve content?
- viewer behavior in presence of congestion?
- what content to place in which CDN node?

more .. in chapter 7

CDN content access: a closer look

Bob (client) requests video <http://netcinema.com/6Y7B23V>

- video stored in CDN at <http://KingCDN.com/NetC6y&B23V>

Case study: Netflix

Chapter 2: outline

2.1 principles of network applications

2.2 Web and HTTP

2.3 electronic mail

- SMTP, POP3, IMAP

2.4 DNS

2.5 P2P applications

2.6 video streaming and content distribution networks

2.7 socket programming with UDP and TCP

Socket programming

Goal: learn how to build client/server application that communicate using sockets

Socket API

- introduced in BSD4.1 UNIX, 1981
- explicitly created, used, released by apps
- client/server paradigm
- two types of transport service via socket API:
 - unreliable datagram
 - reliable, byte stream-oriented

socket

a *host-local*,
application-created,
OS-controlled interface
(a "door") into which
application process can
both send and
receive messages to/from
another application
process

Socket programming

goal: learn how to build client/server applications that communicate using sockets

socket: door between application process and end-end-transport protocol

Socket programming

Two socket types for two transport services:

- **UDP:** unreliable datagram
- **TCP:** reliable, byte stream-oriented

Application Example:

1. client reads a line of characters (data) from its keyboard and sends data to server
2. server receives the data and converts characters to uppercase
3. server sends modified data to client
4. client receives modified data and displays line on its screen

Socket programming *with* UDP

UDP: no “connection” between client & server

- no handshaking before sending data
- sender explicitly attaches IP destination address and port # to each packet
- receiver extracts sender IP address and port# from received packet

UDP: transmitted data may be lost or received out-of-order

Application viewpoint:

- UDP provides *unreliable* transfer of groups of bytes (“datagrams”) between client and server

Client/server socket interaction: UDP

server (running on serverIP)

create socket, port= x:
`serverSocket =
socket(AF_INET,SOCK_DGRAM)`

↓
read datagram from
`serverSocket`

↓
write reply to
`serverSocket`
specifying
client address,
port number

client

create socket:
`clientSocket =
socket(AF_INET,SOCK_DGRAM)`

↓
Create datagram with server IP and
port=x; send datagram via
`clientSocket`

↓
read datagram from
`clientSocket`

↓
close
`clientSocket`

Example app: UDP client

Python UDPClient

include Python's socket
library

```
from socket import *  
serverName = 'hostname'  
serverPort = 12000
```

create UDP socket for
server

```
clientSocket = socket(AF_INET,  
                      SOCK_DGRAM)
```

get user keyboard
input

```
message = raw_input('Input lowercase sentence:')
```

Attach server name, port to
message; send into socket

```
clientSocket.sendto(message.encode(),  
                    (serverName, serverPort))
```

read reply characters from
socket into string

```
modifiedMessage, serverAddress =  
clientSocket.recvfrom(2048)
```

print out received string
and close socket

```
print modifiedMessage.decode()  
clientSocket.close()
```

Example app: UDP server

Python UDPServer

```
from socket import *
```

```
serverPort = 12000
```

create UDP socket → `serverSocket = socket(AF_INET, SOCK_DGRAM)`

bind socket to local port
number 12000 → `serverSocket.bind(("", serverPort))`

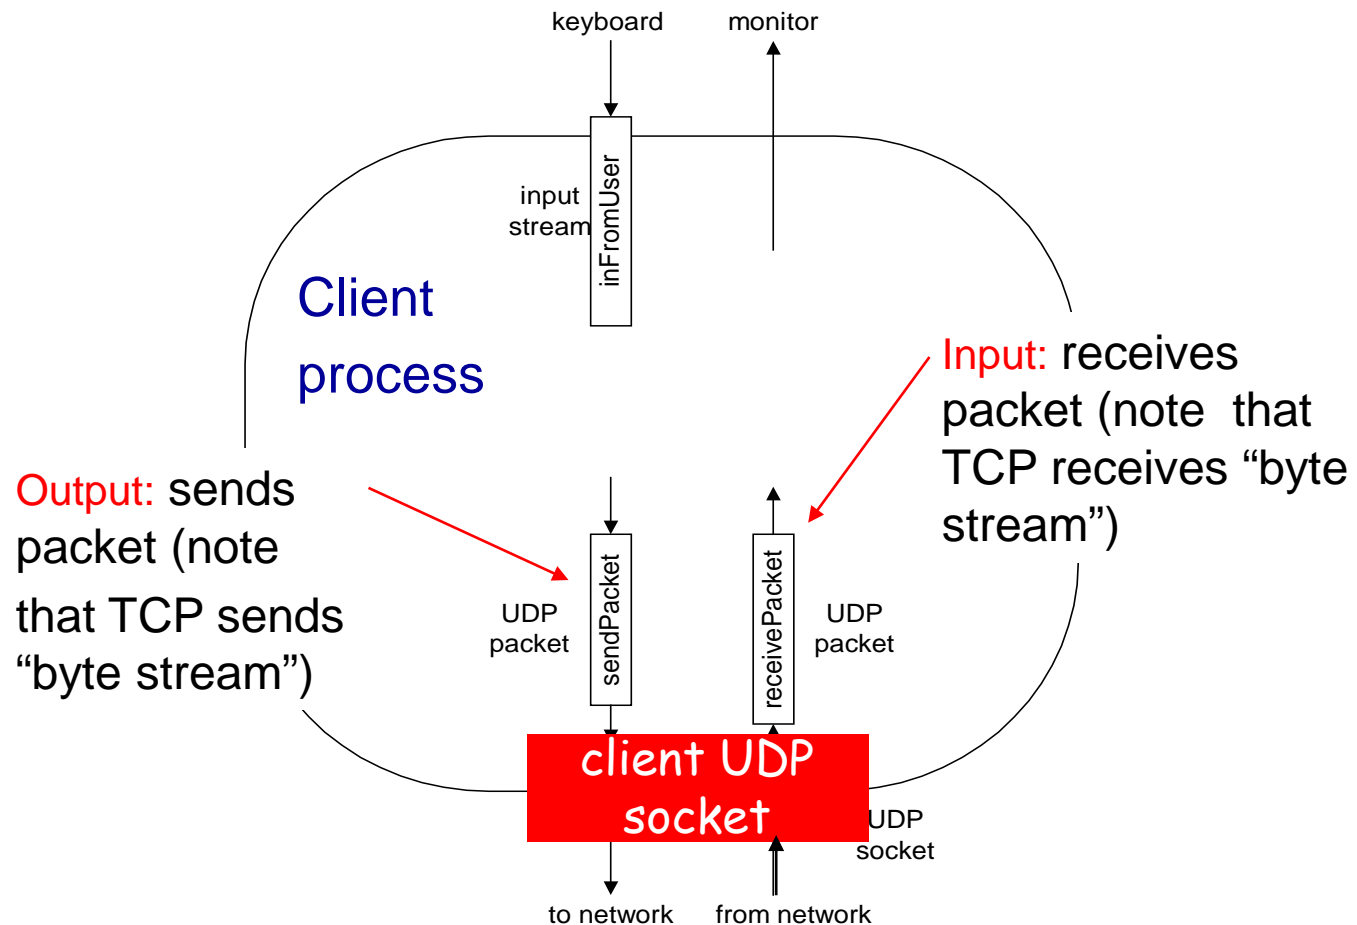

```
print ("The server is ready to receive")
```

loop forever → `while True:`

Read from UDP socket into
message, getting client's
address (client IP and port) → `message, clientAddress = serverSocket.recvfrom(2048)`
`modifiedMessage = message.decode().upper()`

send upper case string
back to this client → `serverSocket.sendto(modifiedMessage.encode(),
clientAddress)`

Example: Java client (UDP)

Example: Java client (UDP)

```
import java.io.*;  
import java.net.*;
```

```
class UDPClient {  
    public static void main(String args[]) throws Exception  
    {
```

create
input stream

```
        BufferedReader inFromUser =  
            new BufferedReader(new InputStreamReader(System.in));
```

create
client socket

```
        DatagramSocket clientSocket = new DatagramSocket();
```

translate
hostname to IP
address using DNS

```
        InetAddress IPAddress = InetAddress.getByName("hostname");
```

```
        byte[] sendData = new byte[1024];  
        byte[] receiveData = new byte[1024];
```

```
        String sentence = inFromUser.readLine();  
        sendData = sentence.getBytes();
```

Example: Java client (UDP), cont.

create datagram
with data-to-send,
length, IP addr, port

send datagram
to server

read datagram
from server

```
DatagramPacket sendPacket =  
    new DatagramPacket(sendData, sendData.length, IPAddress, 9876);  
  
clientSocket.send(sendPacket);  
  
DatagramPacket receivePacket =  
    new DatagramPacket(receiveData, receiveData.length);  
  
clientSocket.receive(receivePacket);  
  
String modifiedSentence =  
    new String(receivePacket.getData());  
  
System.out.println("FROM SERVER:" + modifiedSentence);  
clientSocket.close();  
}  
}
```

Example: Java server (UDP)

```
import java.io.*;  
import java.net.*;
```

```
class UDPServer {  
    public static void main(String args[]) throws Exception  
    {
```

create
datagram socket
at port 9876

```
DatagramSocket serverSocket = new DatagramSocket(9876);
```

```
byte[] receiveData = new byte[1024];  
byte[] sendData = new byte[1024];
```

```
while(true)  
{
```

create space for
received datagram

```
DatagramPacket receivePacket =  
    new DatagramPacket(receiveData, receiveData.length);
```

receive
datagram

```
serverSocket.receive(receivePacket);
```

Example: Java server (UDP), cont

```
String sentence = new String(receivePacket.getData());
```

get IP addr
port #, of
sender

```
    InetAddress IPAddress = receivePacket.getAddress();  
    int port = receivePacket.getPort();
```

```
String capitalizedSentence = sentence.toUpperCase();
```

```
sendData = capitalizedSentence.getBytes();
```

create datagram
to send to client

```
    DatagramPacket sendPacket =  
        new DatagramPacket(sendData, sendData.length, IPAddress,  
                             port);
```

write out
datagram
to socket

```
    serverSocket.send(sendPacket);  
}
```

end of while loop,
loop back and wait for
another datagram

Socket-programming using TCP

Socket: a door between application process and end-end-transport protocol (UCP or TCP)

TCP service: reliable transfer of *bytes* from one process to another

Socket programming *with TCP*

client must contact server

- server process must first be running
- server must have created socket (door) that welcomes client's contact

client contacts server by:

- Creating TCP socket, specifying IP address, port number of server process
- *when client creates socket:* client TCP establishes connection to server TCP

- when contacted by client, *server TCP creates new socket* for server process to communicate with that particular client
 - allows server to talk with multiple clients
 - source port numbers used to distinguish clients (more in Chap 3)

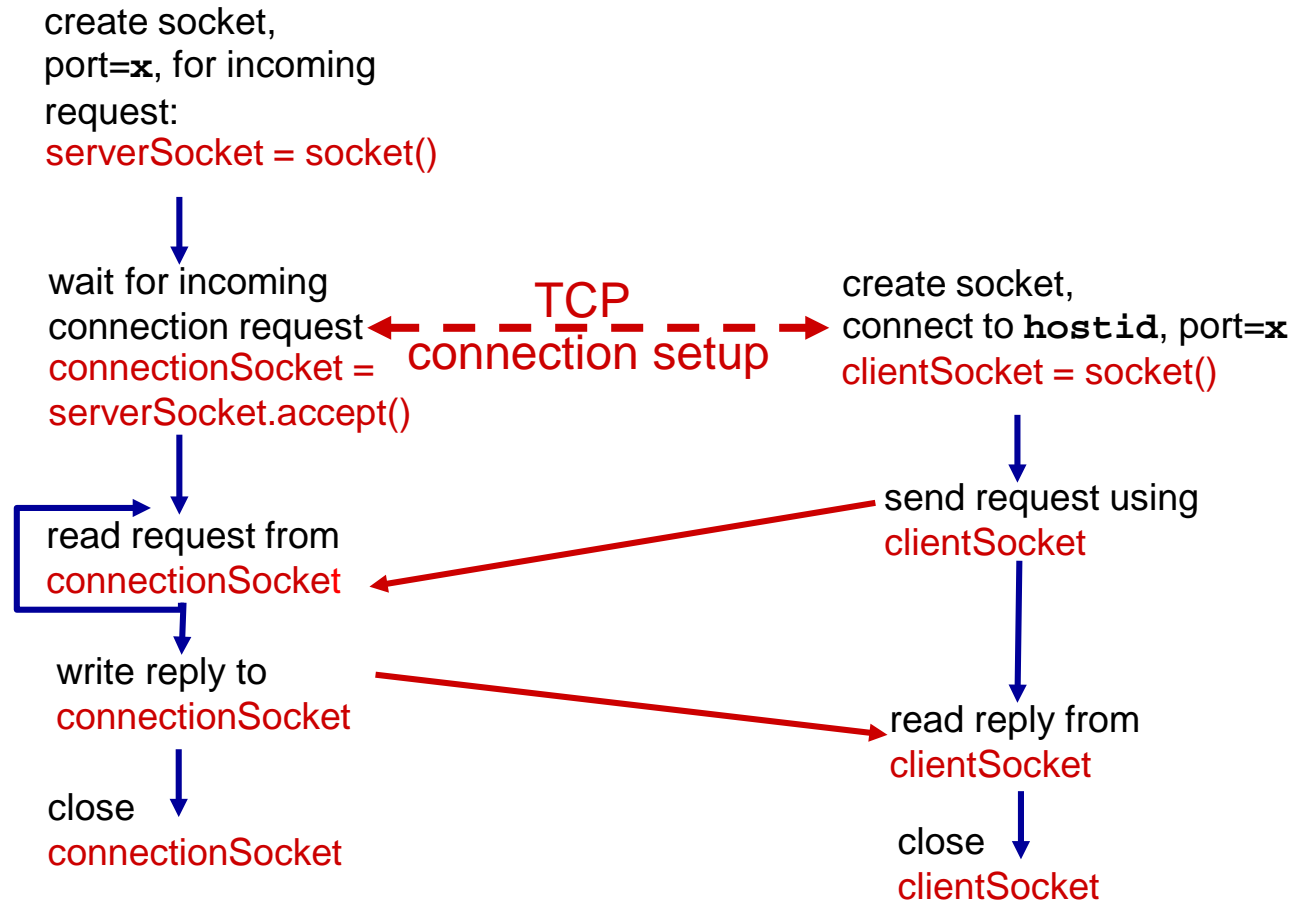

application viewpoint:

TCP provides reliable, in-order byte-stream transfer (“pipe”) between client and server

Client/server socket interaction: TCP

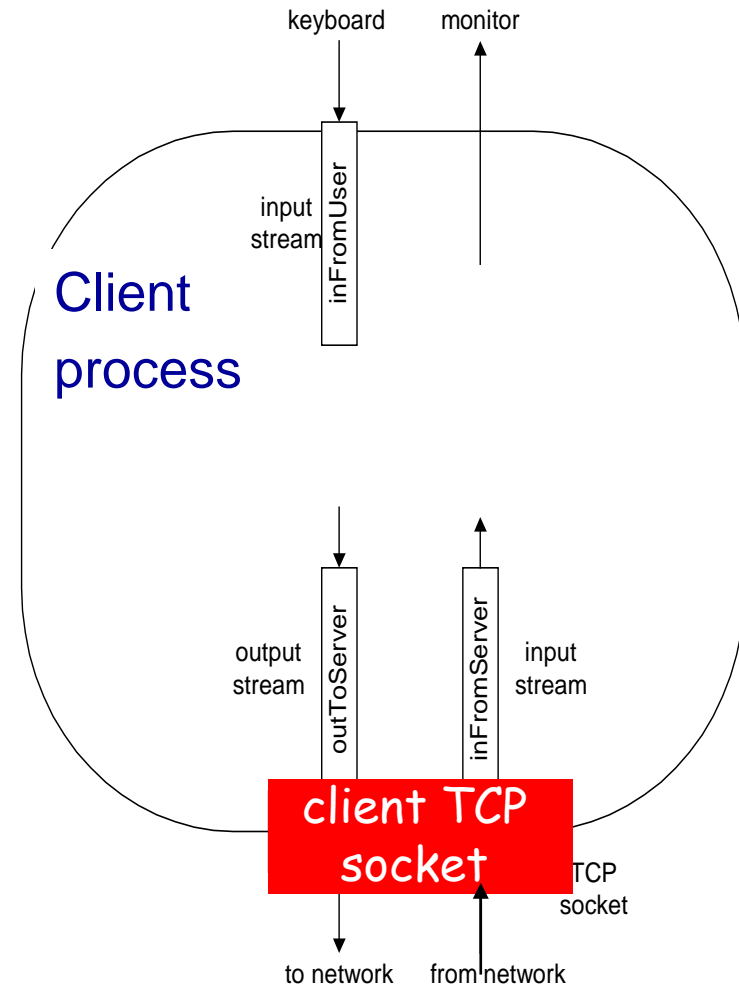

server (running on `hostid`)

client

Stream jargon

- **stream** is a sequence of characters that flow into or out of a process.
- **input stream** is attached to some input source for the process, e.g., keyboard or socket.
- **output stream** is attached to an output source, e.g., monitor or socket.

Socket programming with TCP

Example client-server app:

- 1) client reads line from standard input (`inFromUser` stream) , sends to server via socket (`outToServer` stream)
- 2) server reads line from socket
- 3) server converts line to uppercase, sends back to client
- 4) client reads, prints modified line from socket (`inFromServer` stream)

Example app: TCP client

Python TCPClient

```
from socket import *
```

```
serverName = 'servername'
```

```
serverPort = 12000
```

create TCP socket for
server, remote port 12000

```
clientSocket = socket(AF_INET, SOCK_STREAM)
```

```
clientSocket.connect((serverName, serverPort))
```

```
sentence = raw_input('Input lowercase sentence:')
```

No need to attach server
name, port

```
clientSocket.send(sentence.encode())
```

```
modifiedSentence = clientSocket.recv(1024)
```

```
print ('From Server:', modifiedSentence.decode())
```

```
clientSocket.close()
```

Example app: TCP server

Python TCPServer

create TCP welcoming
socket

server begins listening for
incoming TCP requests

loop forever

server waits on accept()
for incoming requests, new
socket created on return

read bytes from socket (but
not address as in UDP)

close connection to this
client (but *not* welcoming
socket)

```
from socket import *
serverPort = 12000
serverSocket = socket(AF_INET, SOCK_STREAM)
serverSocket.bind(('', serverPort))
serverSocket.listen(1)
print 'The server is ready to receive'

while True:
    connectionSocket, addr = serverSocket.accept()
    sentence = connectionSocket.recv(1024).decode()
    capitalizedSentence = sentence.upper()
    connectionSocket.send(capitalizedSentence.
                           encode())
    connectionSocket.close()
```

Example: Java client (TCP)

```
import java.io.*;
import java.net.*;
class TCPCClient {
```

← This package defines Socket() and ServerSocket() classes

```
    public static void main(String argv[]) throws Exception
    {
```

```
        String sentence;
        String modifiedSentence;
```

create
input stream →

```
        BufferedReader inFromUser =
            new BufferedReader(new InputStreamReader(System.in));
```

create
clientSocket object
of type Socket,
connect to server →

```
        Socket clientSocket = new Socket("hostname", 6789);
```

server name,
e.g., www.umass.edu
server port #

create
output stream
attached to socket →

```
        DataOutputStream outToServer =
            new DataOutputStream(clientSocket.getOutputStream());
```

Example: Java client (TCP), cont.

create
input stream
attached to socket → `BufferedReader inFromServer =
new BufferedReader(new
InputStreamReader(clientSocket.getInputStream()));`

`sentence = inFromUser.readLine();`

send line
to server → `outToServer.writeBytes(sentence + '\n');`

read line
from server → `modifiedSentence = inFromServer.readLine();`

`System.out.println("FROM SERVER: " + modifiedSentence);`

close socket
(clean up behind yourself!) → `clientSocket.close();`

`}`
`}`

Example: Java server (TCP)

```
import java.io.*;  
import java.net.*;
```

```
class TCPServer {
```

```
    public static void main(String argv[]) throws Exception  
    {
```

```
        String clientSentence;  
        String capitalizedSentence;
```

create
welcoming socket
at port 6789

```
        ServerSocket welcomeSocket = new ServerSocket(6789);
```

wait, on welcoming
socket accept() method
for client contact create,
new socket on return

```
        while(true) {
```

```
            Socket connectionSocket = welcomeSocket.accept();
```

create input
stream, attached
to socket

```
            BufferedReader inFromClient =
```

```
            new BufferedReader(new  
                InputStreamReader(connectionSocket.getInputStream()));
```

Example: Java server (TCP), cont

create output stream, attached to socket → `DataOutputStream outToClient = new DataOutputStream(connectionSocket.getOutputStream());`

read in line from socket → `clientSentence = inFromClient.readLine();`

`capitalizedSentence = clientSentence.toUpperCase() + '\n';`

write out line to socket → `outToClient.writeBytes(capitalizedSentence);`

`}`
`}`
`}`

end of while loop,
loop back and wait for
another client connection

Chapter 2: summary

our study of network apps now complete!

- application architectures
 - client-server
 - P2P
- application service requirements:
 - reliability, bandwidth, delay
- Internet transport service model
 - connection-oriented, reliable: TCP
 - unreliable, datagrams: UDP
- specific protocols:
 - HTTP
 - SMTP, POP, IMAP
 - DNS
 - P2P: BitTorrent
- video streaming, CDNs
- socket programming:
TCP, UDP sockets

Chapter 2: summary

most importantly: learned about protocols!

- typical request/reply message exchange:
 - client requests info or service
 - server responds with data, status code
- message formats:
 - *headers*: fields giving info about data
 - *data*: info(payload) being communicated

important themes:

- control vs. messages
 - in-band, out-of-band
- centralized vs. decentralized
- stateless vs. stateful
- reliable vs. unreliable message transfer
- “complexity at network edge”
