CS 280: Network Security

(Abbreviated version of Ch 8)

John Magee 12 December 2016

Chapter 8: Network Security

Chapter goals:

- understand principles of network security:
 - cryptography and its many uses beyond "confidentiality"
 - authentication
 - message integrity
- security in practice:
 - firewalls and intrusion detection systems
 - security in application, transport, network, link layers

Chapter 8 roadmap

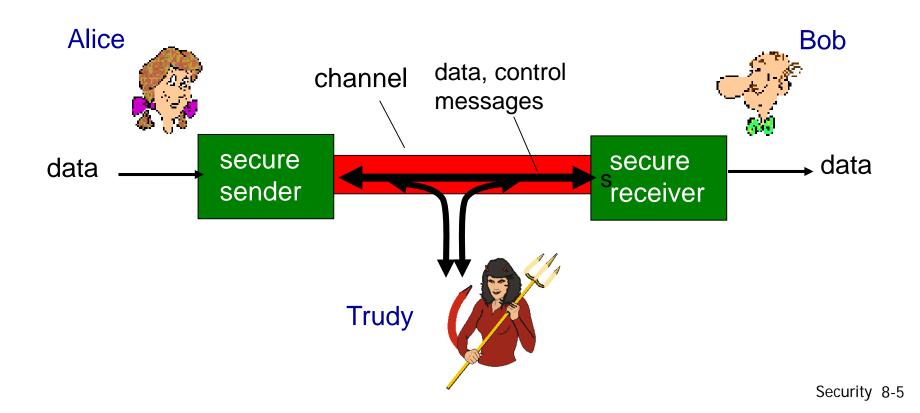

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity, authentication
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

What is network security?

- confidentiality: only sender, intended receiver should "understand" message contents
 - sender encrypts message
 - receiver decrypts message
- authentication: sender, receiver want to confirm identity of each other
- message integrity: sender, receiver want to ensure message not altered (in transit, or afterwards) without detection
- access and availability: services must be accessible and available to users

Friends and enemies: Alice, Bob, Trudy

- well-known in network security world
- Bob, Alice (lovers!) want to communicate "securely"
- Trudy (intruder) may intercept, delete, add messages

Who might Bob, Alice be?

- well, real-life Bobs and Alices!
- Web browser/server for electronic transactions (e.g., on-line purchases)
- on-line banking client/server
- DNS servers
- routers exchanging routing table updates
- other examples?

There are bad guys (and girls) out there!

Q: What can a "bad guy" do?

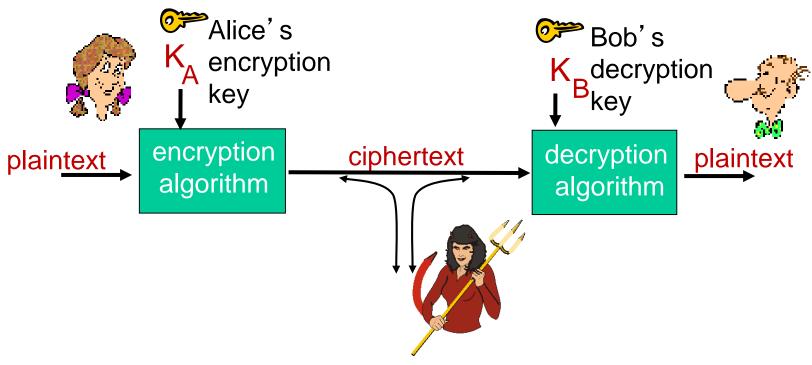

A: A lot! See section 1.6

- eavesdrop: intercept messages
- actively insert messages into connection
- impersonation: can fake (spoof) source address in packet (or any field in packet)
- hijacking: "take over" ongoing connection by removing sender or receiver, inserting himself in place
- denial of service: prevent service from being used by others (e.g., by overloading resources)

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity, authentication
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

The language of cryptography

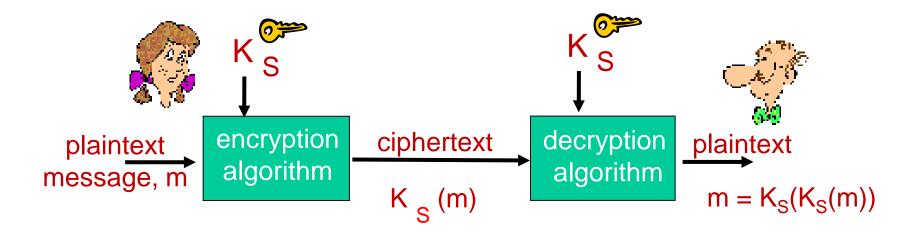

m plaintext message $K_A(m)$ ciphertext, encrypted with key K_A $m = K_B(K_A(m))$

Breaking an encryption scheme

- cipher-text only attack: Trudy has ciphertext she can analyze
- two approaches:
 - brute force: search through all keys
 - statistical analysis

- known-plaintext attack:
 Trudy has plaintext
 corresponding to ciphertext
 - e.g., in monoalphabetic cipher, Trudy determines pairings for a,l,i,c,e,b,o,
- chosen-plaintext attack:
 Trudy can get ciphertext for chosen plaintext

Symmetric key cryptography

symmetric key crypto: Bob and Alice share same (symmetric) key: K_S

- e.g., key is knowing substitution pattern in mono alphabetic substitution cipher
- Q: how do Bob and Alice agree on key value?

Simple encryption scheme

substitution cipher: substituting one thing for another

monoalphabetic cipher: substitute one letter for another

```
plaintext: abcdefghijklmnopqrstuvwxyz

ciphertext: mnbvcxzasdfghjklpoiuytrewq
```

```
e.g.: Plaintext: bob. i love you. alice ciphertext: nkn. s gktc wky. mgsbc
```

Encryption key: mapping from set of 26 letters to set of 26 letters

A more sophisticated encryption approach

- n substitution ciphers, $M_1, M_2, ..., M_n$
- cycling pattern:
 - e.g., n=4: M_1, M_3, M_4, M_3, M_2 ; M_1, M_3, M_4, M_3, M_2 ; ...
- for each new plaintext symbol, use subsequent substitution pattern in cyclic pattern
 - dog: d from M₁, o from M₃, g from M₄

Encryption key: n substitution ciphers, and cyclic pattern

• key need not be just n-bit pattern

Symmetric key crypto: DES

DES: Data Encryption Standard

- US encryption standard [NIST 1993]
- 56-bit symmetric key, 64-bit plaintext input
- block cipher with cipher block chaining
- how secure is DES?
 - DES Challenge: 56-bit-key-encrypted phrase decrypted (brute force) in less than a day
 - no known good analytic attack
- making DES more secure:
 - 3DES: encrypt 3 times with 3 different keys

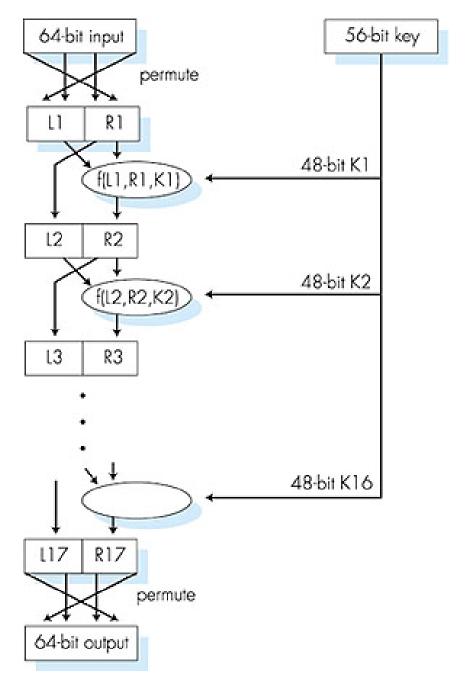

Symmetric key crypto: DES

DES operation

initial permutation

16 identical "rounds" of function application, each using different 48 bits of key

final permutation

AES: Advanced Encryption Standard

- symmetric-key NIST standard, replaced DES (Nov 2001)
- processes data in 128 bit blocks
- 128, 192, or 256 bit keys
- brute force decryption (try each key) taking I sec on DES, takes I49 trillion years for AES

Public Key Cryptography

symmetric key crypto

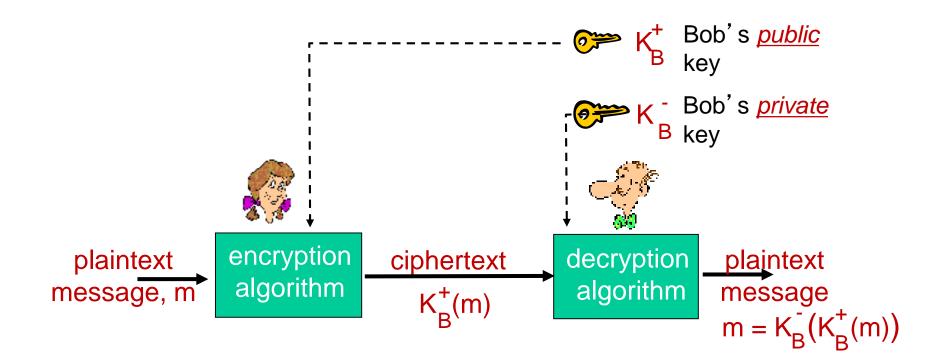

- requires sender, receiver know shared secret key
- Q: how to agree on key in first place (particularly if never "met")?

public key crypto

- radically different approach [Diffie-Hellman76, RSA78]
- sender, receiver do not share secret key
- public encryption key known to all
- private decryption key known only to receiver

Public key cryptography

Public key encryption algorithms

requirements:

- 1 need $K_B^+(\cdot)$ and $K_B^-(\cdot)$ such that $K_B^-(K_B^+(m)) = m$
- given public key K_B⁺, it should be impossible to compute private key K_B

RSA: Rivest, Shamir, Adelson algorithm

RSA: Creating public/private key pair

- 1. choose two large prime numbers p, q. (e.g., 1024 bits each)
- 2. compute n = pq, z = (p-1)(q-1)
- 3. choose e (with e < n) that has no common factors with z (e, z are "relatively prime").
- 4. choose d such that ed-1 is exactly divisible by z. (in other words: ed mod z = 1).
- 5. public key is (n,e). private key is (n,d).

RSA: encryption, decryption

- 0. given (n,e) and (n,d) as computed above
 - 1. to encrypt message m (<n), compute $c = m^e \mod n$
- 2. to decrypt received bit pattern, c, compute $m = c^d \mod n$

magic
$$m = (m^e \mod n)^d \mod n$$
 happens!

RSA: another important property

The following property will be very useful later:

$$K_{B}(K_{B}(m)) = m = K_{B}(K_{B}(m))$$

use public key first, followed by private key use private key first, followed by public key

result is the same!

Why
$$K_{B}(K_{B}(m)) = m = K_{B}(K_{B}(m))$$
?

follows directly from modular arithmetic:

```
(m^e \mod n)^d \mod n = m^{ed} \mod n
= m^{de} \mod n
= (m^d \mod n)^e \mod n
```

Why is RSA secure?

- suppose you know Bob's public key (n,e). How hard is it to determine d?
- essentially need to find factors of n without knowing the two factors p and q
 - fact: factoring a big number is hard

RSA in practice: session keys

- exponentiation in RSA is computationally intensive
- DES is at least 100 times faster than RSA
- use public key crypto to establish secure connection, then establish second key – symmetric session key – for encrypting data

session key, K_S

- Bob and Alice use RSA to exchange a symmetric key K_S
- once both have K_S, they use symmetric key cryptography

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity, authentication
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

Authentication

Goal: Bob wants Alice to "prove" her identity to him

Protocol ap 1.0: Alice says "I am Alice"

Failure scenario??

Authentication

Goal: Bob wants Alice to "prove" her identity to him

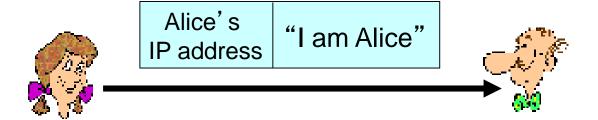

Protocol ap 1.0: Alice says "I am Alice"

in a network,
Bob can not "see" Alice,
so Trudy simply declares
herself to be Alice

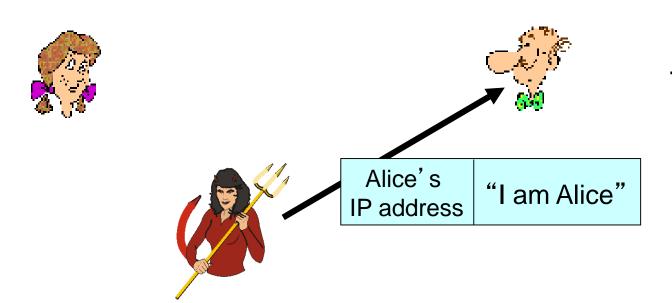

Protocol ap2.0: Alice says "I am Alice" in an IP packet containing her source IP address

Failure scenario??

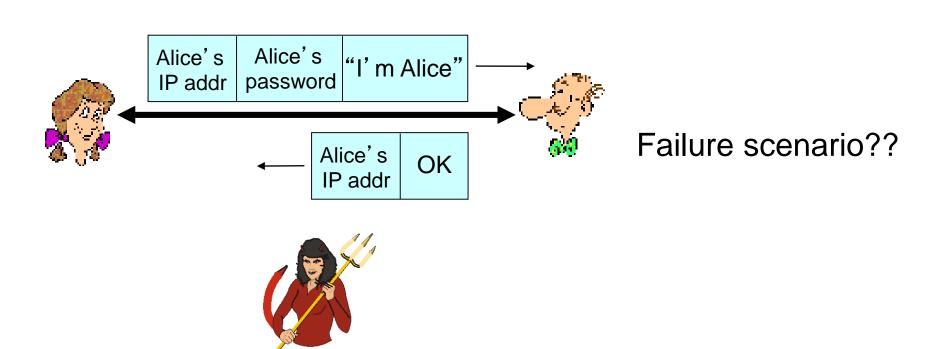

Protocol ap2.0: Alice says "I am Alice" in an IP packet containing her source IP address

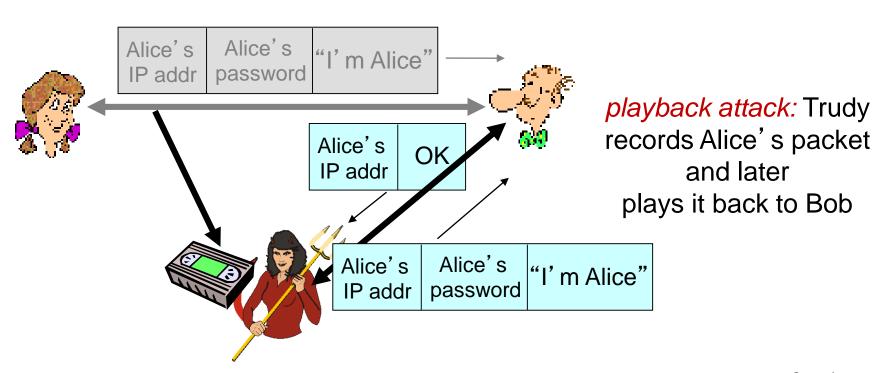

Trudy can create
a packet
"spoofing"
Alice's address

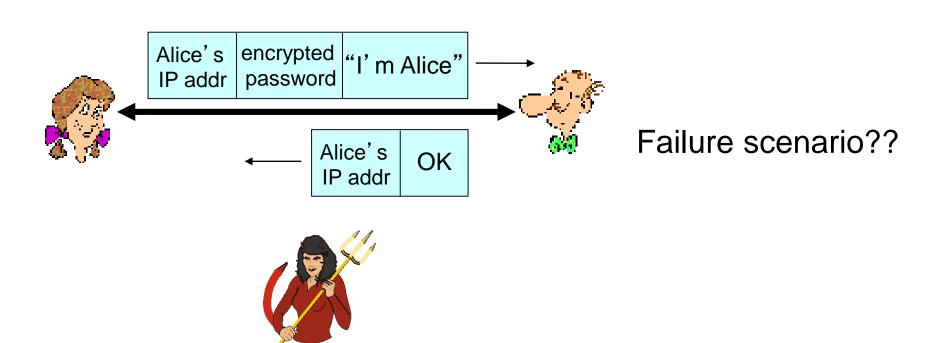

Protocol ap3.0: Alice says "I am Alice" and sends her secret password to "prove" it.

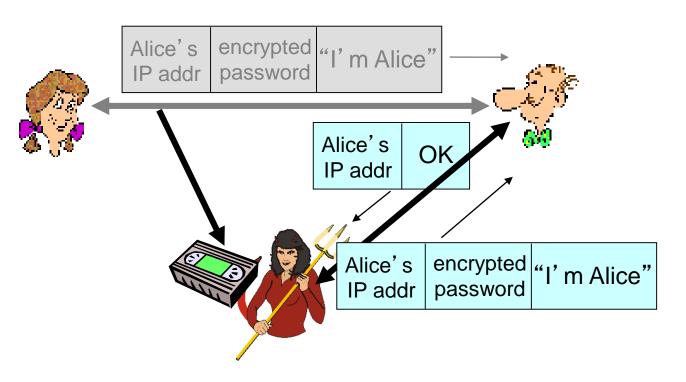

Protocol ap3.0: Alice says "I am Alice" and sends her secret password to "prove" it.

Protocol ap3.1: Alice says "I am Alice" and sends her encrypted secret password to "prove" it.

Protocol ap3.1: Alice says "I am Alice" and sends her encrypted secret password to "prove" it.

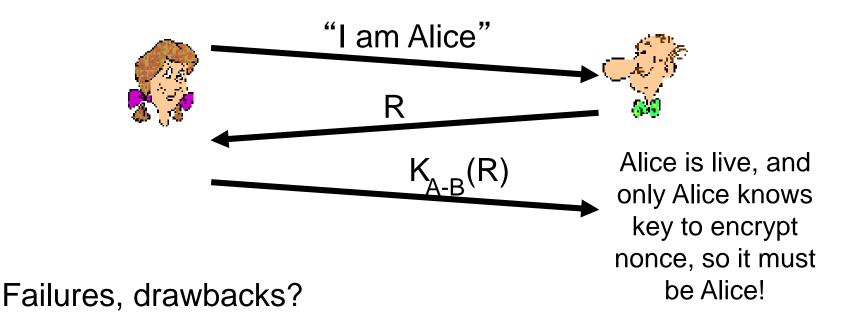

record and playback still works!

Goal: avoid playback attack

nonce: number (R) used only once-in-a-lifetime

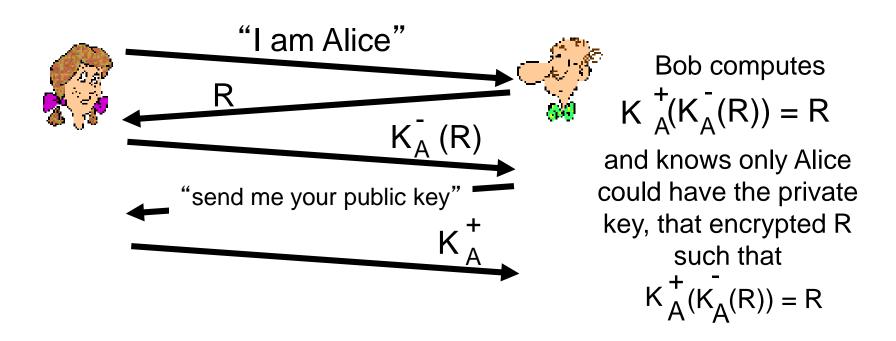

ap4.0: to prove Alice "live", Bob sends Alice nonce, R. Alice must return R, encrypted with shared secret key

Authentication: ap5.0

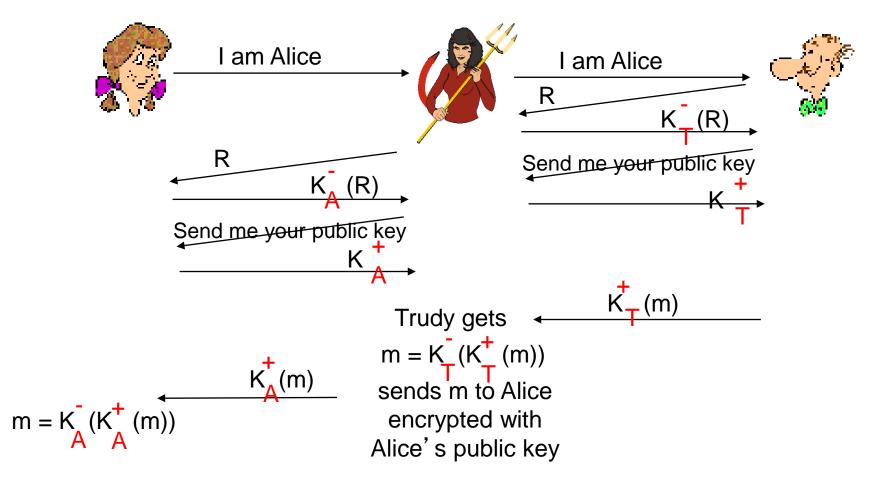

ap4.0 requires shared symmetric key

can we authenticate using public key techniques? ap5.0: use nonce, public key cryptography

ap5.0: security hole

man (or woman) in the middle attack: Trudy poses as Alice (to Bob) and as Bob (to Alice)

ap5.0: security hole

man (or woman) in the middle attack: Trudy poses as Alice (to Bob) and as Bob (to Alice)

difficult to detect:

- Bob receives everything that Alice sends, and vice versa. (e.g., so Bob, Alice can meet one week later and recall conversation!)
- problem is that Trudy receives all messages as well!

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity, authentication
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

Digital signatures

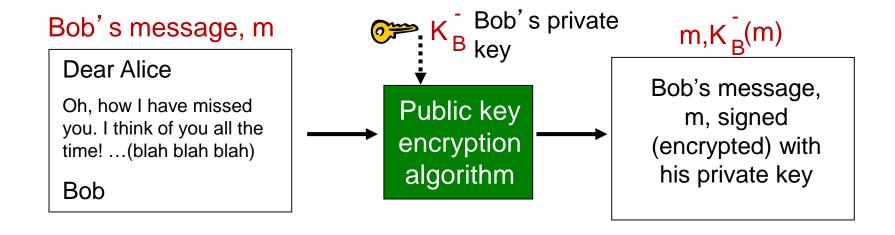

cryptographic technique analogous to hand-written signatures:

- sender (Bob) digitally signs document, establishing he is document owner/creator.
- verifiable, nonforgeable: recipient (Alice) can prove to someone that Bob, and no one else (including Alice), must have signed document

Digital signatures

simple digital signature for message m:

• Bob signs m by encrypting with his private key $K_{\overline{B}}$, creating "signed" message, $K_{\overline{B}}$ (m)

Digital signatures

- suppose Alice receives msg m, with signature: m, $K_B(m)$
- Alice verifies m signed by Bob by applying Bob's public key K_B to ${}^{\dagger}K_B(m)$ then checks $K_B(K_B^{\dagger}(m)) = m$.
- If $K_B^+(K_B^-(m)) = m$, whoever signed m must have used Bob's private key.

Alice thus verifies that:

- Bob signed m
- no one else signed m
- Bob signed m and not m '

non-repudiation:

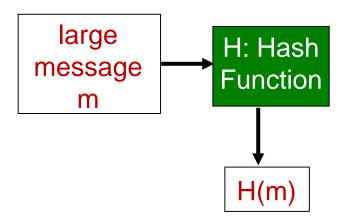

✓ Alice can take m, and signature $K_B(m)$ to court and prove that Bob signed m

Message digests

computationally expensive to public-key-encrypt long messages

goal: fixed-length, easy-to-compute digital "fingerprint"

 apply hash function H to m, get fixed size message digest, H(m).

Hash function properties:

- many-to-l
- produces fixed-size msg digest (fingerprint)
- given message digest x, computationally infeasible to find m such that x = H(m)

Internet checksum: poor crypto hash function

Internet checksum has some properties of hash function:

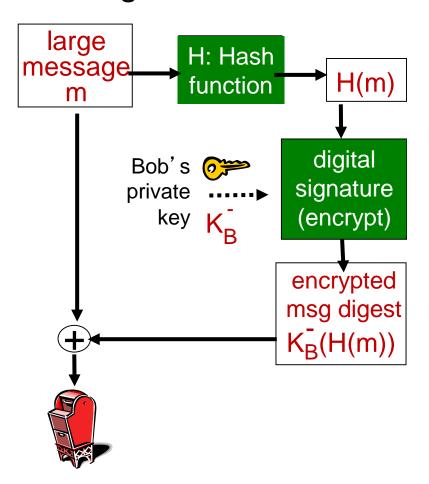

- produces fixed length digest (16-bit sum) of message
- is many-to-one

But given message with given hash value, it is easy to find another message with same hash value:

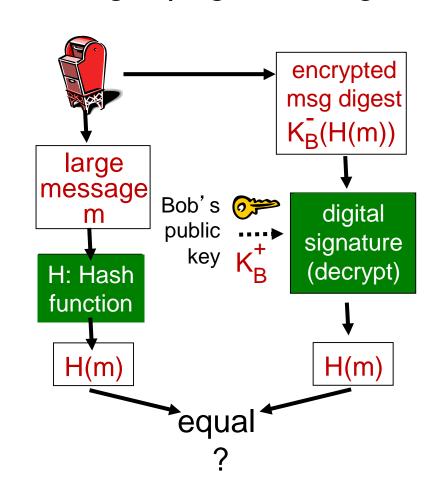

<u>message</u>	ASCII format	<u>message</u>	ASCII format
I O U 1	49 4F 55 31	I O U <u>9</u>	49 4F 55 <u>39</u>
00.9	30 30 2E 39	00. <u>1</u>	30 30 2E <u>31</u>
9 B O B	39 42 D2 42	9 B O B	39 42 D2 42
	B2 C1 D2 AC —	different messages	B2 C1 D2 AC
		but identical checksums!	

Digital signature = signed message digest

Bob sends digitally signed message:

Alice verifies signature, integrity of digitally signed message:

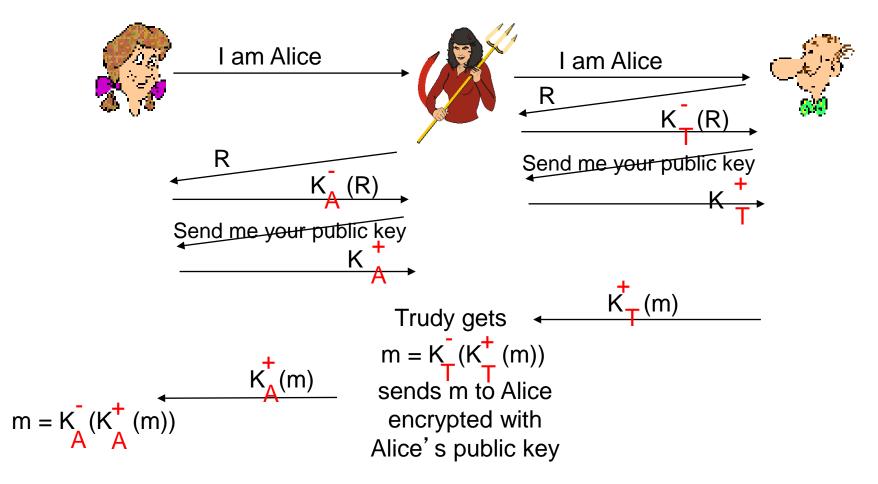

Hash function algorithms

- MD5 hash function widely used (RFC 1321)
 - computes 128-bit message digest in 4-step process.
 - arbitrary I28-bit string x, appears difficult to construct msg m whose MD5 hash is equal to x
- SHA-I is also used
 - US standard [NIST, FIPS PUB 180-1]
 - 160-bit message digest

Recall: ap5.0 security hole

man (or woman) in the middle attack: Trudy poses as Alice (to Bob) and as Bob (to Alice)

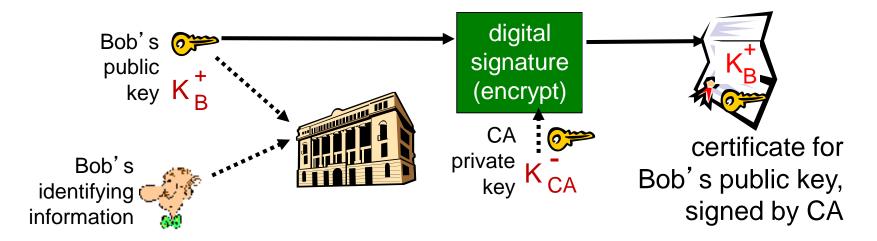

Public-key certification

- motivation: Trudy plays pizza prank on Bob
 - Trudy creates e-mail order:
 Dear Pizza Store, Please deliver to me four pepperoni pizzas. Thank you, Bob
 - Trudy signs order with her private key
 - Trudy sends order to Pizza Store
 - Trudy sends to Pizza Store her public key, but says it's Bob's public key
 - Pizza Store verifies signature; then delivers four pepperoni pizzas to Bob
 - Bob doesn't even like pepperoni

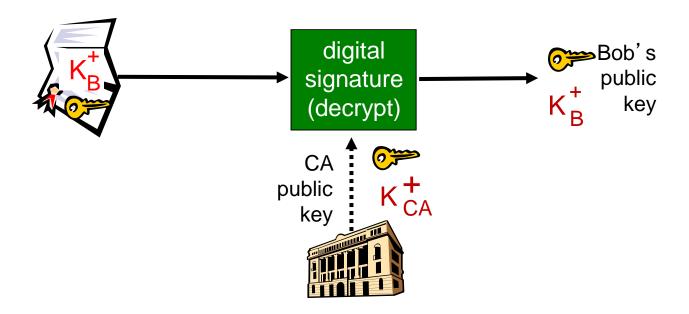

Certification authorities

- certification authority (CA): binds public key to particular entity, E.
- E (person, router) registers its public key with CA.
 - E provides "proof of identity" to CA.
 - CA creates certificate binding E to its public key.
 - certificate containing E's public key digitally signed by CA CA says "this is E's public key"

Certification authorities

- when Alice wants Bob's public key:
 - gets Bob's certificate (Bob or elsewhere).
 - apply CA's public key to Bob's certificate, get Bob's public key

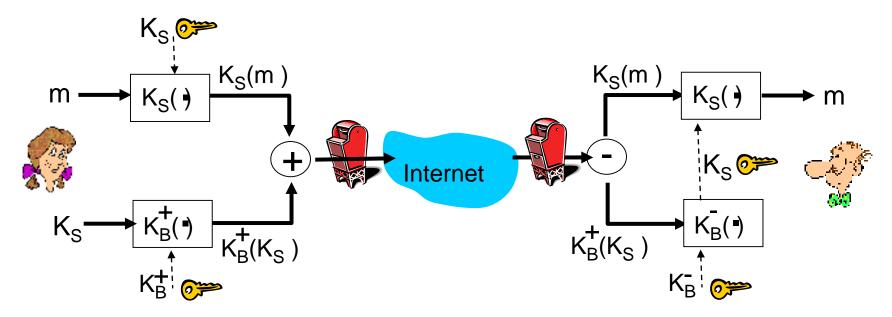

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity, authentication
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

Secure e-mail

Alice wants to send confidential e-mail, m, to Bob.

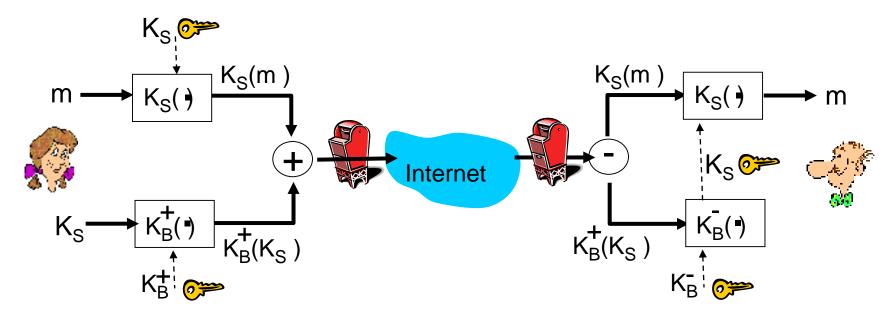

Alice:

- generates random symmetric private key, K_S
- encrypts message with K_S (for efficiency)
- also encrypts K_S with Bob's public key
- sends both $K_S(m)$ and $K_B(K_S)$ to Bob

Secure e-mail

Alice wants to send confidential e-mail, m, to Bob.

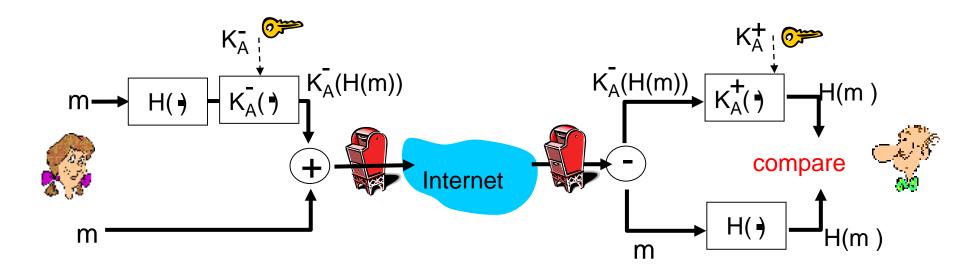

Bob:

- uses his private key to decrypt and recover K_S
- uses K_S to decrypt $K_S(m)$ to recover m

Secure e-mail (continued)

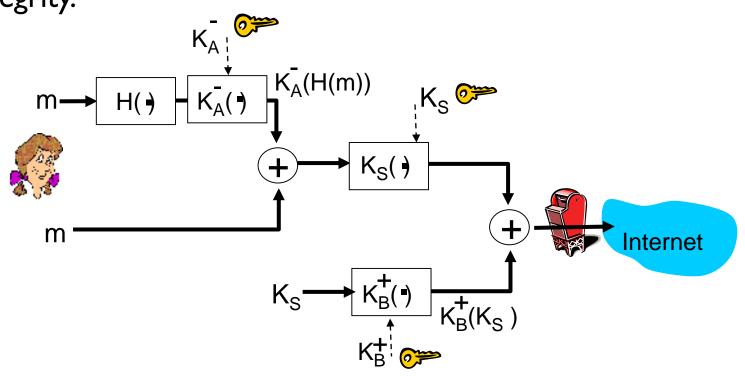

Alice wants to provide sender authentication message integrity

- Alice digitally signs message
- sends both message (in the clear) and digital signature

Secure e-mail (continued)

Alice wants to provide secrecy, sender authentication, message integrity.

Alice uses three keys: her private key, Bob's public key, newly created symmetric key

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity
- 8.4 Securing e-mail
- 8.5 Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

SSL: Secure Sockets Layer

- widely deployed security protocol
 - supported by almost all browsers, web servers
 - https
 - billions \$/year over SSL
- mechanisms: [Woo 1994], implementation: Netscape
- variation -TLS: transport layer security, RFC 2246
- provides
 - confidentiality
 - integrity
 - authentication

- original goals:
 - Web e-commerce transactions
 - encryption (especially credit-card numbers)
 - Web-server authentication
 - optional client authentication
 - minimum hassle in doing business with new merchant
- available to all TCP applications
 - secure socket interface

SSL and TCP/IP

Application
TCP

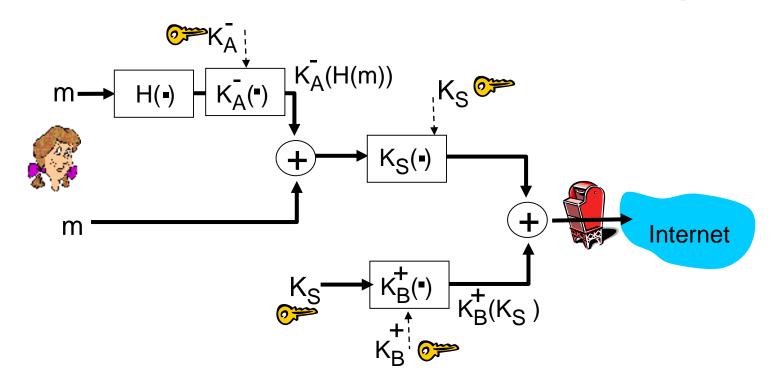

normal application

Application
SSL
TCP
IP

application with SSL

- SSL provides application programming interface (API) to applications
- C and Java SSL libraries/classes readily available

Could do something like PGP:

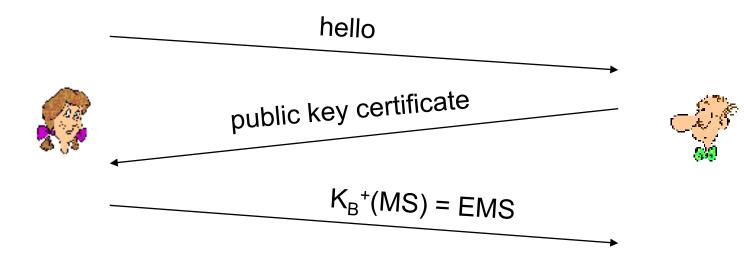

- but want to send byte streams & interactive data
- want set of secret keys for entire connection
- want certificate exchange as part of protocol: handshake phase

Toy SSL: a simple secure channel

- handshake: Alice and Bob use their certificates, private keys to authenticate each other and exchange shared secret
- key derivation: Alice and Bob use shared secret to derive set of keys
- data transfer: data to be transferred is broken up into series of records
- connection closure: special messages to securely close connection

Toy: a simple handshake

MS: master secret

EMS: encrypted master secret

SSL cipher suite

- cipher suite
 - public-key algorithm
 - symmetric encryption algorithm
 - MAC algorithm
- SSL supports several cipher suites
- negotiation: client, server agree on cipher suite
 - client offers choice
 - server picks one

common SSL symmetric ciphers

- DES Data Encryption Standard: block
- 3DES Triple strength: block
- RC2 Rivest Cipher 2: block
- RC4 Rivest Cipher 4: stream

SSL Public key encryption

RSA

Real SSL: handshake (1)

Purpose

- I. server authentication
- 2. negotiation: agree on crypto algorithms
- 3. establish keys
- 4. client authentication (optional)

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

What is network-layer confidentiality?

between two network entities:

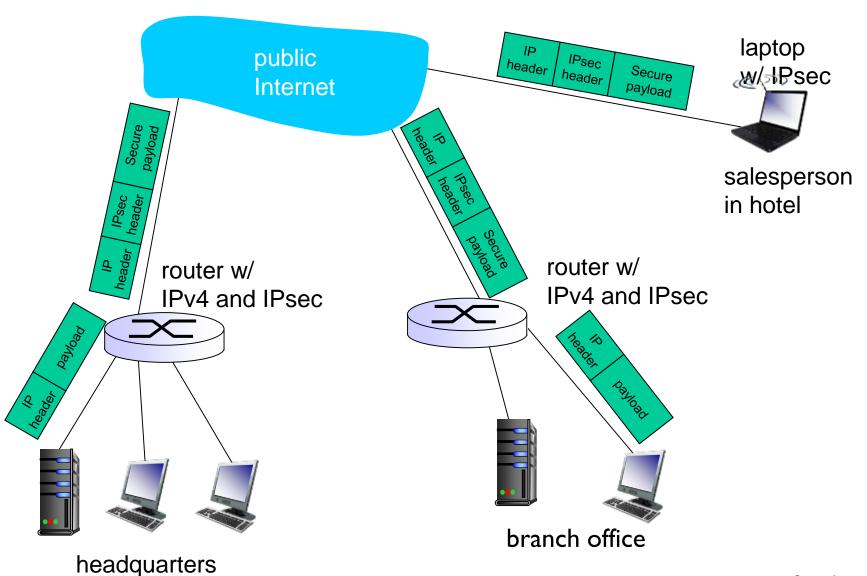

- sending entity encrypts datagram payload, payload could be:
 - TCP or UDP segment, ICMP message, OSPF message
- all data sent from one entity to other would be hidden:
 - web pages, e-mail, P2P file transfers, TCP SYN packets
 ...
- "blanket coverage"

Virtual Private Networks (VPNs)

motivation:

- institutions often want private networks for security.
 - costly: separate routers, links, DNS infrastructure.
- VPN: institution's inter-office traffic is sent over public Internet instead
 - encrypted before entering public Internet
 - logically separate from other traffic

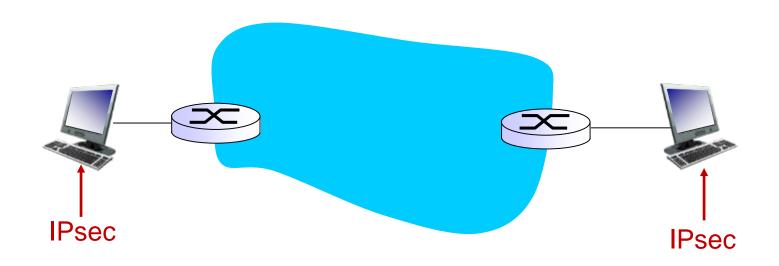

Virtual Private Networks (VPNs)

IPsec services

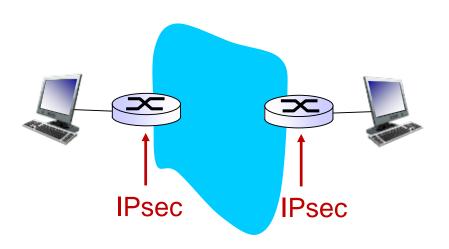

- data integrity
- origin authentication
- replay attack prevention
- confidentiality
- two protocols providing different service models:
 - AH
 - ESP

IPsec transport mode

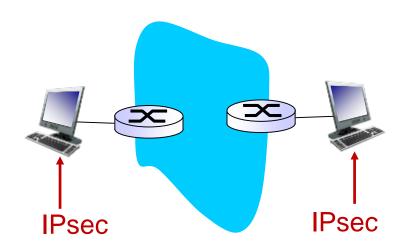

- IPsec datagram emitted and received by end-system
- protects upper level protocols

IPsec – tunneling mode

edge routers IPsecaware

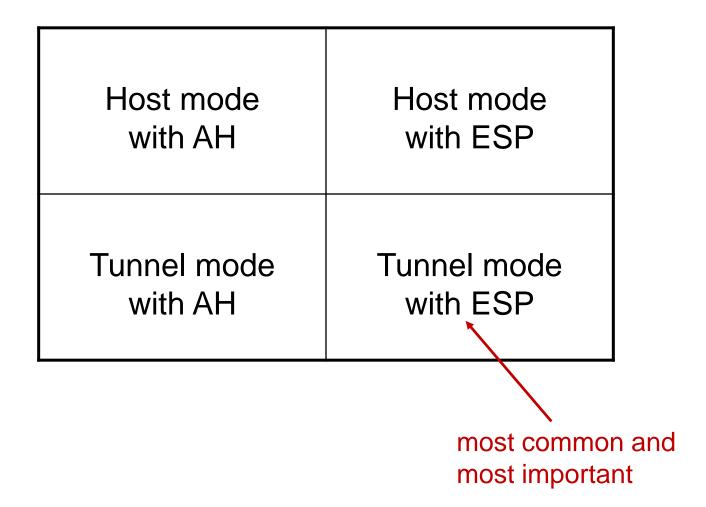

hosts IPsec-aware

Two IPsec protocols

- Authentication Header (AH) protocol
 - provides source authentication & data integrity but not confidentiality
- Encapsulation Security Protocol (ESP)
 - provides source authentication, data integrity, and confidentiality
 - more widely used than AH

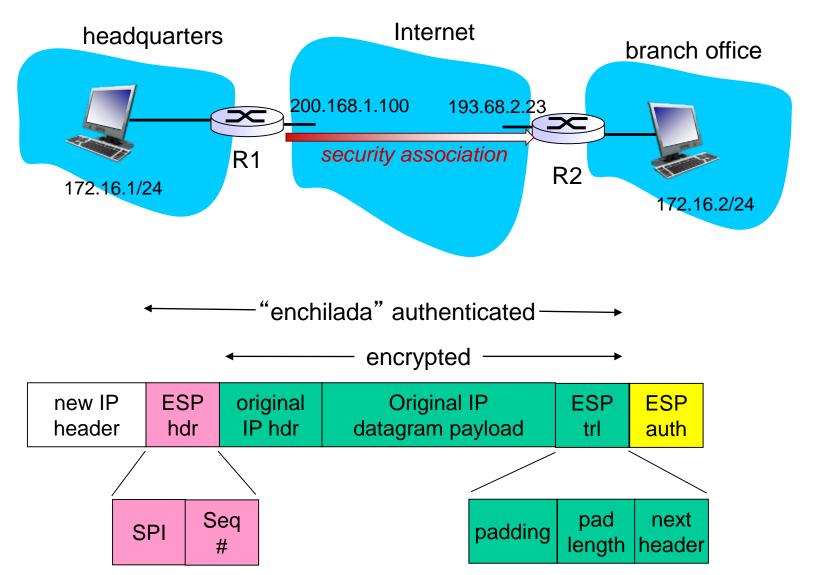

Four combinations are possible!

Security associations (SAs)

- before sending data, "security association (SA)" established from sending to receiving entity
 - SAs are simplex: for only one direction
- ending, receiving entitles maintain state information about SA
 - recall: TCP endpoints also maintain state info
 - IP is connectionless; IPsec is connection-oriented!
- how many SAs in VPN w/ headquarters, branch office, and n traveling salespeople?

What happens?

Summary: IPsec services

- suppose Trudy sits somewhere between R1 and R2. she doesn't know the keys.
 - will Trudy be able to see original contents of datagram? How about source, dest IP address, transport protocol, application port?
 - flip bits without detection?
 - masquerade as RI using RI's IP address?
 - replay a datagram?

IPsec summary

- IKE (Internet Key Exchange) message exchange for algorithms, secret keys, SPI numbers
- either AH or ESP protocol (or both)
 - AH provides integrity, source authentication
 - ESP protocol (with AH) additionally provides encryption
- IPsec peers can be two end systems, two routers/firewalls, or a router/firewall and an end system

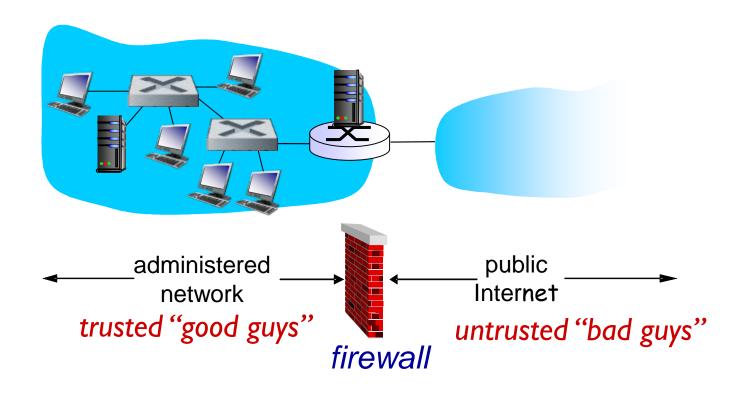

Chapter 8 roadmap

- 8.1 What is network security?
- 8.2 Principles of cryptography
- 8.3 Message integrity
- 8.4 Securing e-mail
- **8.5** Securing TCP connections: SSL
- 8.6 Network layer security: IPsec
- 8.7 Securing wireless LANs
- 8.8 Operational security: firewalls and IDS

Firewalls

firewall

isolates organization's internal net from larger Internet, allowing some packets to pass, blocking others

Firewalls: why

prevent denial of service attacks:

 SYN flooding: attacker establishes many bogus TCP connections, no resources left for "real" connections

prevent illegal modification/access of internal data

- e.g., attacker replaces CIA's homepage with something else
 allow only authorized access to inside network
 - set of authenticated users/hosts

three types of firewalls:

- stateless packet filters
- stateful packet filters
- application gateways

- internal network connected to Internet via router firewall
- router filters packet-by-packet, decision to forward/drop packet based on:
 - source IP address, destination IP address
 - TCP/UDP source and destination port numbers
 - ICMP message type
 - TCP SYN and ACK bits

Stateless packet filtering: example

- example 1: block incoming and outgoing datagrams with IP protocol field = 17 and with either source or dest port = 23
 - result: all incoming, outgoing UDP flows and telnet connections are blocked
- example 2: block inbound TCP segments with ACK=0.
 - result: prevents external clients from making TCP connections with internal clients, but allows internal clients to connect to outside.

Stateless packet filtering: more examples

Policy	Firewall Setting		
No outside Web access.	Drop all outgoing packets to any IP address, port 80		
No incoming TCP connections, except those for institution's public Web server only.	Drop all incoming TCP SYN packets to any IP except 130.207.244.203, port 80		
Prevent Web-radios from eating up the available bandwidth.	Drop all incoming UDP packets - except DNS and router broadcasts.		
Prevent your network from being used for a smurf DoS attack.	Drop all ICMP packets going to a "broadcast" address (e.g. 130.207.255.255).		
Prevent your network from being tracerouted	Drop all outgoing ICMP TTL expired traffic		

Access Control Lists

ACL: table of rules, applied top to bottom to incoming packets: (action, condition) pairs: looks like OpenFlow forwarding (Ch. 4)!

action	source address	dest address	protocol	source dest port		flag bit
allow	222.22/16	outside of 222.22/16	TCP	> 1023	80	any
allow	outside of 222.22/16	222.22/16	TCP	80 > 1023		ACK
allow	222.22/16	outside of 222.22/16	UDP	> 1023	53	
allow	outside of 222.22/16	222.22/16	UDP	53	> 1023	
deny	all	all	all	all	all	all

Stateful packet filtering

- stateless packet filter: heavy handed tool
 - admits packets that "make no sense," e.g., dest port = 80, ACK bit set, even though no TCP connection established:

action	source address	dest address	protocol	source port	dest port	flag bit
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK

- stateful packet filter: track status of every TCP connection
 - track connection setup (SYN), teardown (FIN): determine whether incoming, outgoing packets "makes sense"
 - timeout inactive connections at firewall: no longer admit packets

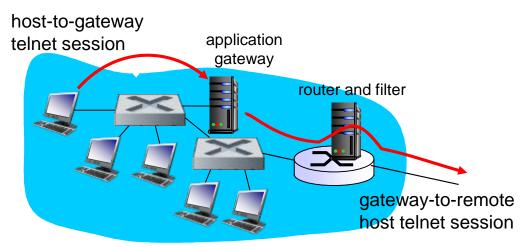

Stateful packet filtering

ACL augmented to indicate need to check connection state table before admitting packet

action	source address	dest address	proto	source port	dest port	flag bit	check conxion
allow	222.22/16	outside of 222.22/16	TCP	> 1023	80	any	
allow	outside of 222.22/16	222.22/16	TCP	80	> 1023	ACK	X
allow	222.22/16	outside of 222.22/16	UDP	> 1023	53		
allow	outside of 222.22/16	222.22/16	UDP	53	> 1023		X
deny	all	all	all	all	all	all	

Application gateways

- filter packets on application data as well as on IP/TCP/UDP fields.
- example: allow select internal users to telnet outside

- I. require all telnet users to telnet through gateway.
- 2. for authorized users, gateway sets up telnet connection to dest host. Gateway relays data between 2 connections
- 3. router filter blocks all telnet connections not originating from gateway.

Limitations of firewalls, gateways

- IP spoofing: router can't know if data "really" comes from claimed source
- if multiple app's. need special treatment, each has own app. gateway
- client software must know how to contact gateway.
 - e.g., must set IP address of proxy in Web browser

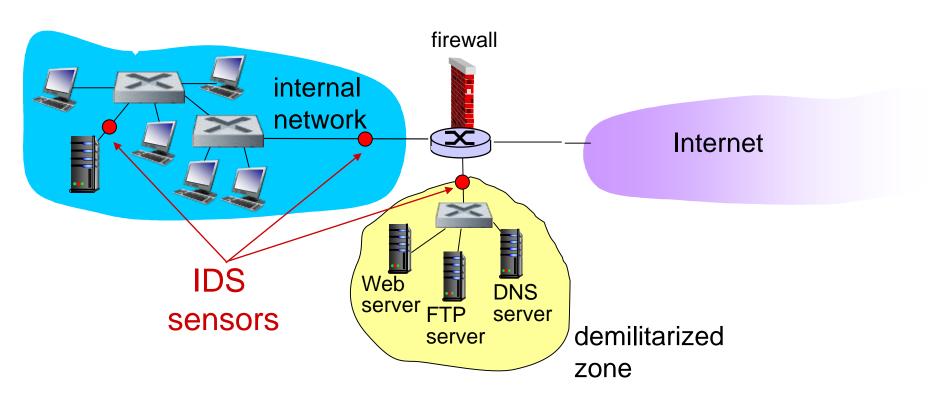

- filters often use all or nothing policy for UDP
- tradeoff: degree of communication with outside world, level of security
- many highly protected sites still suffer from attacks

Intrusion detection systems

- packet filtering:
 - operates on TCP/IP headers only
 - no correlation check among sessions
- IDS: intrusion detection system
 - deep packet inspection: look at packet contents (e.g., check character strings in packet against database of known virus, attack strings)
 - examine correlation among multiple packets
 - port scanning
 - network mapping
 - DoS attack

Intrusion detection systems

multiple IDSs: different types of checking at different locations

Network Security (summary)

basic techniques.....

- cryptography (symmetric and public)
- message integrity
- end-point authentication

.... used in many different security scenarios

- secure email
- secure transport (SSL)
- IP sec
- 802.11

operational security: firewalls and IDS
